

COURS RDFIA deep Image

Matthieu Cord

Sorbonne University

Course Outline – Week timeline

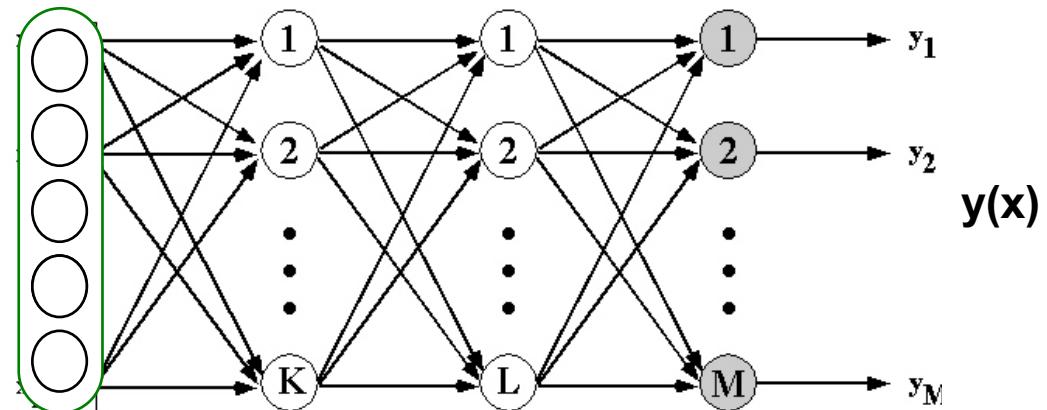

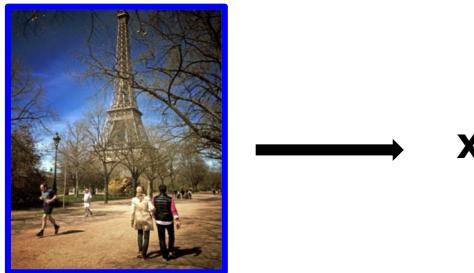

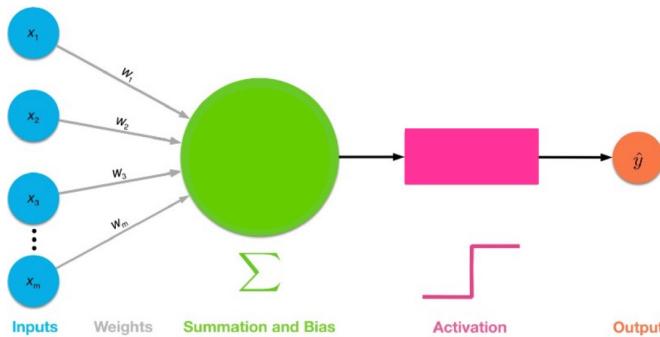

1. Computer Vision basics: Visual (local) feature detection and description, Bag of Word Image representation
 2. Supervised learning: Introduction to Neural Networks (NNs)
 3. Machine Learning basics: Risk, Classification, Datasets, benchmarks and evaluation, Linear classification (SVM)
 4. **Convolutional Nets for visual classification**
 5. Large deep convnets
 6. Very large architectures, beyond ImageNet
 7. Vision Transformers
 8. Transfer learning and domain adaptation
 9. Generative models with GANs
 10. Generative models with conditional GANs
 11. Xai, Applications
 - 12/14 Bayesian deep learning
- 
- Classification- Visual Recognition

Outline

Convolutional Nets for visual classification

1. Recap MLP
2. Convolutional Neural Networks

Recap MLP

MLP example: brute force connection

First Pb: Scalability

Large images => extremely large number of trainable parameters

MLP example: brute force connection

2d Pb: *Stability* of the representation

Expectation:

- *Small deformation in the input space*
=> *similar representations*
- *Large (or unexpected) transfo in the input space*
=> *very dissimilar representations*

Representations:

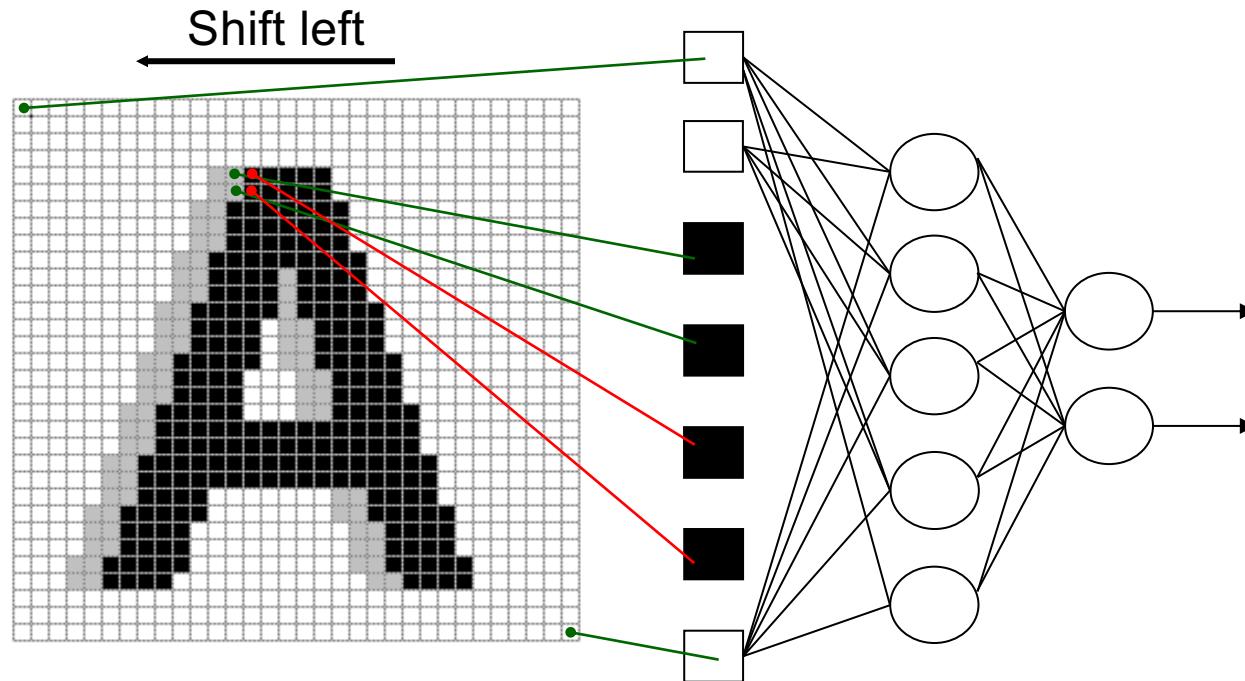

MLP example: brute force connection

Stability: Invariance/Robustness to (local) shifting, scaling, and other forms of (small) distortions?

MLP example: brute force connection

Little or no invariance to shifting, scaling, and other forms of distortion

MLP example: brute force connection

154 input change
from 2 shift left
77 : black to white
77 : white to black

MLP example: brute force connection

Scaling and other forms of distortions => same pb

Conclusion of MLP on raw data

Brute force connection of images as input of MLP NOT a good idea

- No Invariance/Robustness of the representation because topology of the input data completely ignored
- Nb of weights grows largely with the size of the input image

How keep spatial topology?

How to limit the weight number?

Outline

Convolutional Nets for visual classification

1. Recap MLP
2. **Convolutional Neural Networks**

How to limit the weight numbers?

1/ Locally connected neural networks

- **Sparse connectivity:** a hidden unit is only connected to a local patch (weights connected to the patch are called filter or kernel)
- Inspired by biological systems, where a cell is sensitive to a small sub-region of the input space, called a receptive field. Many cells are tiled to cover the entire visual field

How to limit the weight numbers?

2/ Shared Weights

- Hidden nodes at different locations share the same weights
 - greatly reduces the number of parameters to learn
- Keep spatial information in a **2D feature map** (hidden layer map)

- ⇒ Computing responses at hidden nodes equivalent to convoluting input image with a linear filter (learned)
- ⇒ A learned filter as a feature detector

Recap (1D/2D) convolution

1D discrete convolution of input signal $x[n]$, with filter impulse response $h[n]$, and output $y[n]$:

$$y[n] = x[n] * h[n] = \sum_{k=-\infty}^{\infty} x[k] \cdot h[n - k]$$

2D discrete convolution of input signal $x[m,n]$, with filter impulse response $h[m,n]$ (*kernel*), and output $y[m,n]$:

$$y[m, n] = x[m, n] * h[m, n] = \sum_{j=-\infty}^{\infty} \sum_{i=-\infty}^{\infty} x[i, j] \cdot h[m - i, n - j]$$

Example with impulse response (kernel) 3x3, and it's values are a, b, c, d, ... : (0,0) located in the center of the kernel

$$\begin{aligned} y[1, 1] &= \sum_{j=-\infty}^{\infty} \sum_{i=-\infty}^{\infty} x[i, j] \cdot h[1 - i, 1 - j] \\ &= x[0, 0] \cdot h[1, 1] + x[1, 0] \cdot h[0, 1] + x[2, 0] \cdot h[-1, 1] \\ &\quad + x[0, 1] \cdot h[1, 0] + x[1, 1] \cdot h[0, 0] + x[2, 1] \cdot h[-1, 0] \\ &\quad + x[0, 2] \cdot h[1, -1] + x[1, 2] \cdot h[0, -1] + x[2, 2] \cdot h[-1, -1] \end{aligned}$$

	<i>m</i>	-1	0	1
-1	a	b	c	
0	d	e	f	
1	g	h	i	

Ex. of convolution operator

From one to many filters

1 filter => 1 feature map (corresponding to 1 visual pattern)

To detect spatial distributions of multiple visual patterns: Multiple filters

M filters => M feature maps! Get richer description

From one to many filters

M filters => M feature maps

Rq: not many weights but many neurons! => memory issues will appear

What does replicating the feature detectors achieve?

- Equivariant activities (Hinton Ex): Replicated features do not make the neural activities invariant to translation. The activities are equivariant.

Map representation
by one filter

image

translated
representation

translated
image

⇒ How to get invariance to 2D spatial transformation of the input?

Getting (more) local Invariance

(local) spatial **POOLING** of the outputs of replicated feature detectors:

- Averaging neighboring replicated detectors to give a single output to the next level
- Max pooling: Taking the maximum in a neighboring

Get a small amount of translational invariance
at each level

Reducing the number of inputs to the next layer of
feature extraction

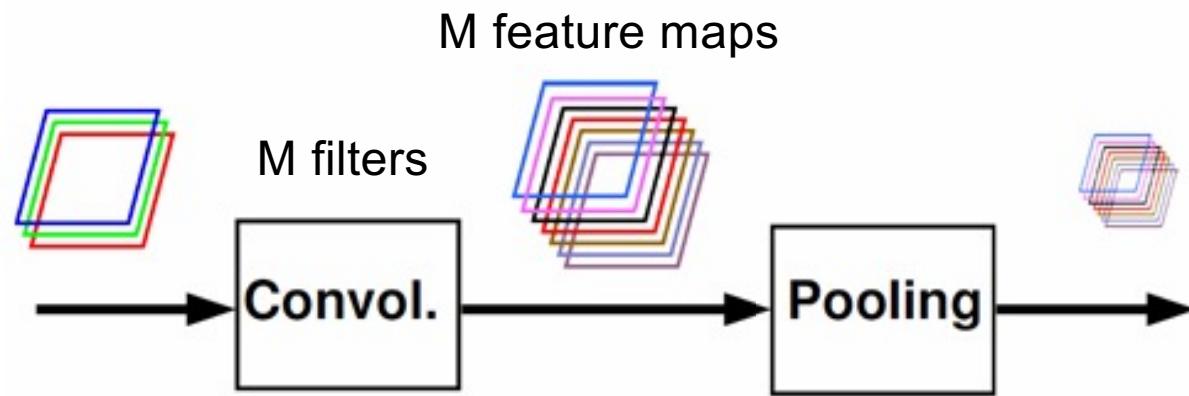

$$y_{ij} = \frac{1}{4}(x_{2i,2j} + x_{2i+1,2j} + x_{2i,2j+1} + x_{2i+1,2j+1})$$

=> Stability OK (at least for local shift) for Convolutional Net!

To sum up:

Color images: 3D kernels for filtering

$m \times n \times d$ parameters per filter
Idem for any layer i to layer $i+1$

LCN: Local Contrast Normalization

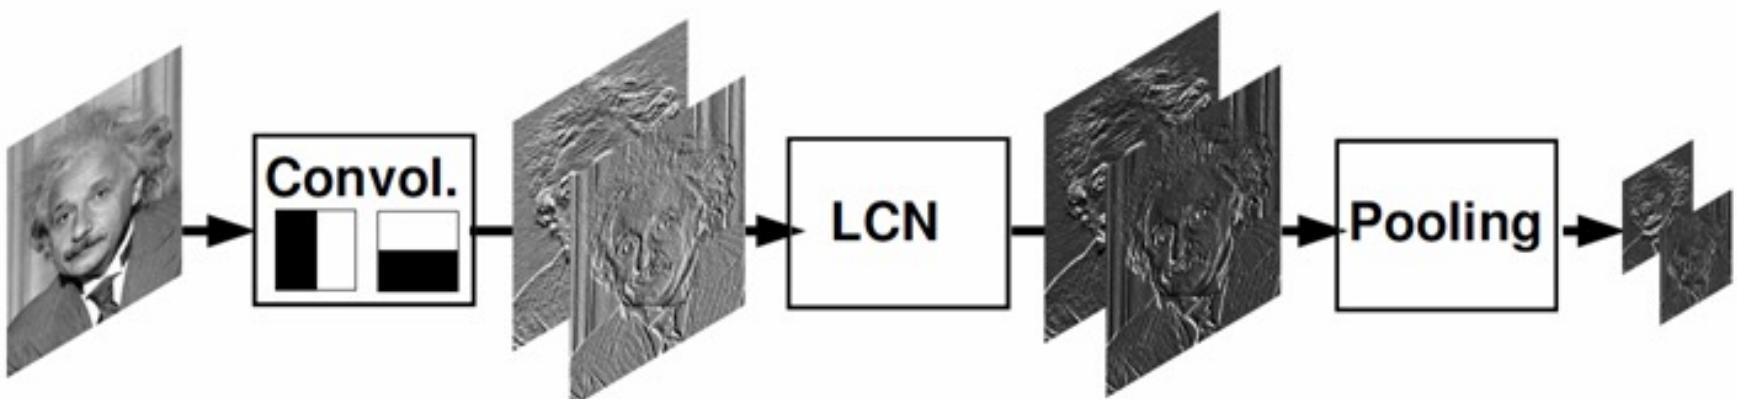

Normalization within a neighborhood along both spatial and feature dimensions

$$h_{i+1,x,y,k} = \frac{h_{i,x,y,k} - m_{i,N(x,y,k)}}{\sigma_{i,N(x,y,k)}}$$

=> Very important for training large nets to carefully consider normalization within mini-batches [S. Ioffe, C. Szegedy 2015]

1st stage of convolutional neural networks

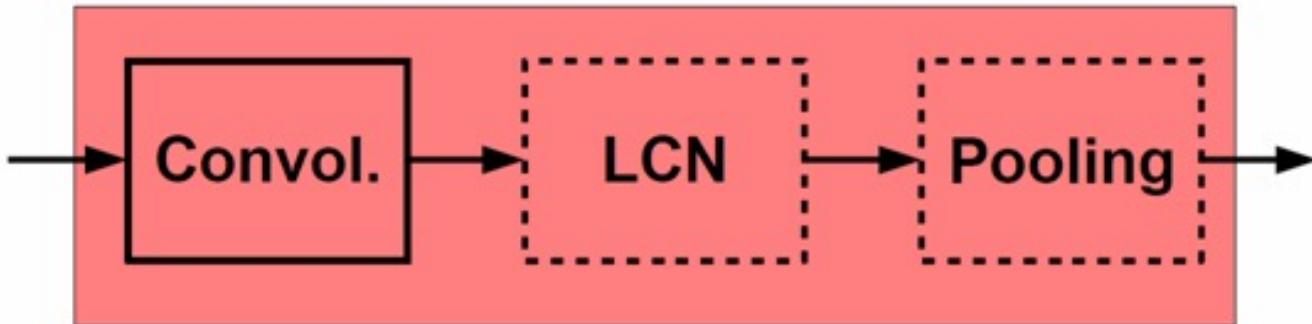

Example with only two filters.

Ranzato CVPR'13

1st stage of convolutional neural networks

One stage (zoom)

A hidden unit in the first hidden layer is influenced by a small neighborhood (equal to size of filter).

Ranzato CVPR'13

1st stage of convolutional neural networks

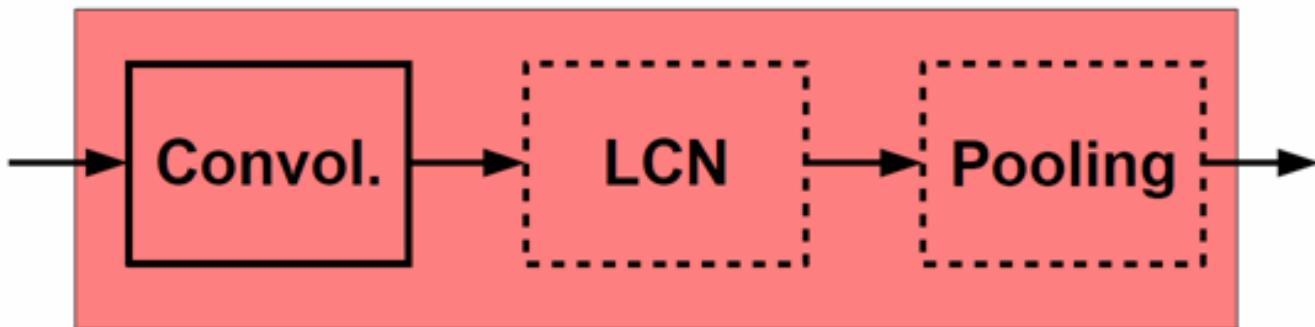

One stage (zoom)

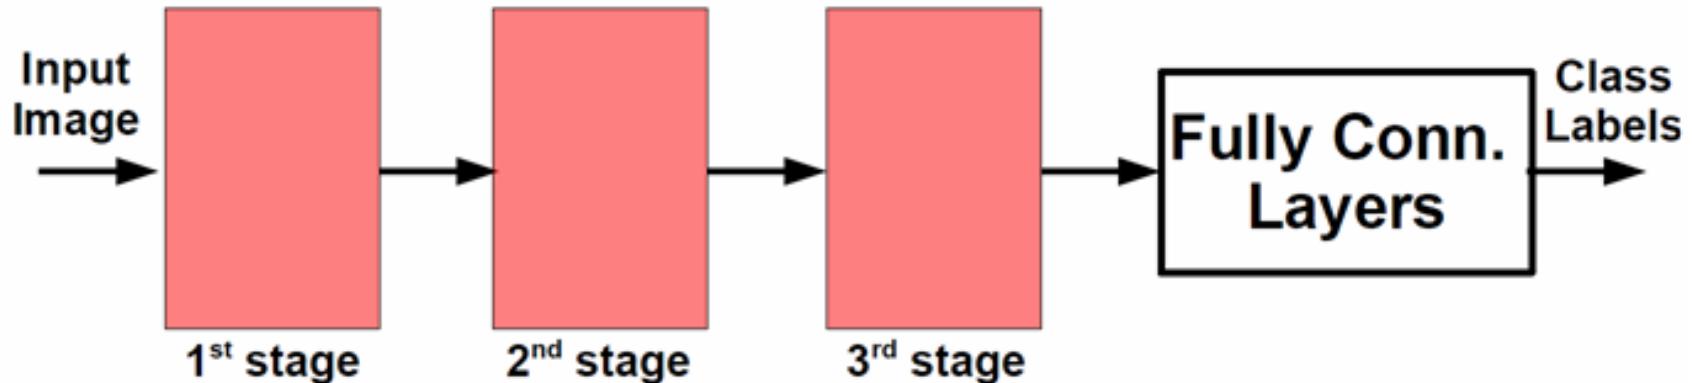

A hidden unit after the pooling layer is influenced by a larger neighborhood
(it depends on filter sizes and the sizes of pooling regions)

Full ConvNet architecture

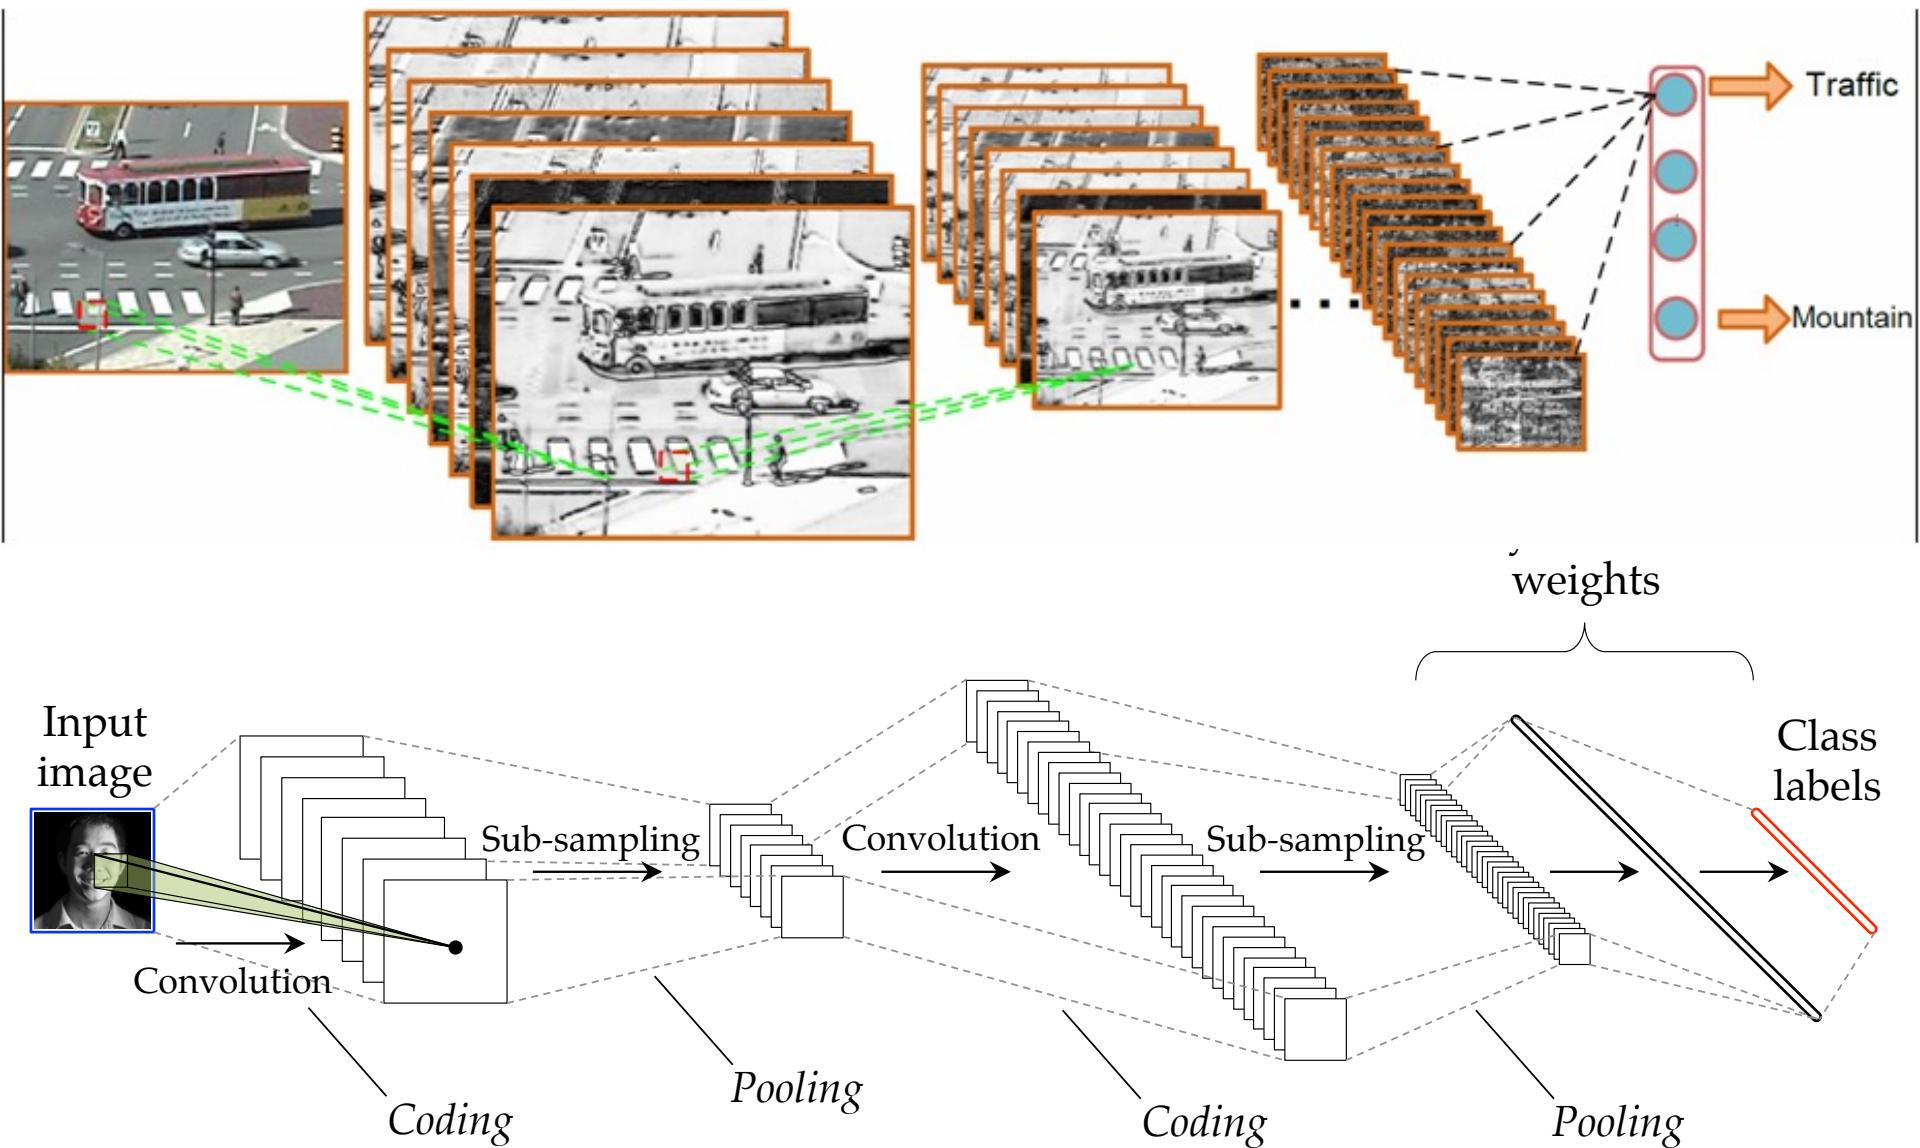

One stage (zoom)

Whole system

To sum up: Full ConvNet architecture

To sum up: Full ConvNet architecture

ConvNet (CNN): feed-forward network with

- ability to extract topological properties from image
- designed to recognize visual patterns

Working directly from pixel images with (no/minimal) preprocessing

Trained with back-propagation

Outline

Convolutional Nets for visual classification

1. Recap MLP
2. Convolutional Neural Networks
3. **Examples: LeNet5, AlexNet**

Example: LeNet5

Introduced by Y. LeCun

Raw image of 32×32 pixels as input

Example: LeNet5

- C1,C3,C5 : Convolutional layer
- 5×5 Convolution matrix
- S2 , S4 : Subsampling layer = Pooling+stride s=2
=> Subsampling by factor 2
- F6 : Fully connected layer

LeNet5

All the units of the layers up to F6 have a sigmoidal activation function

LeNet5

About 187,000 connections

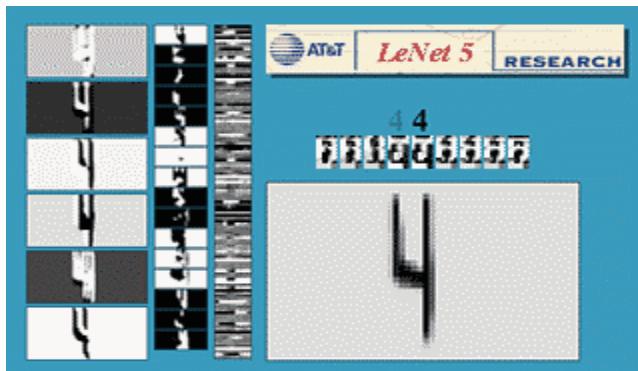

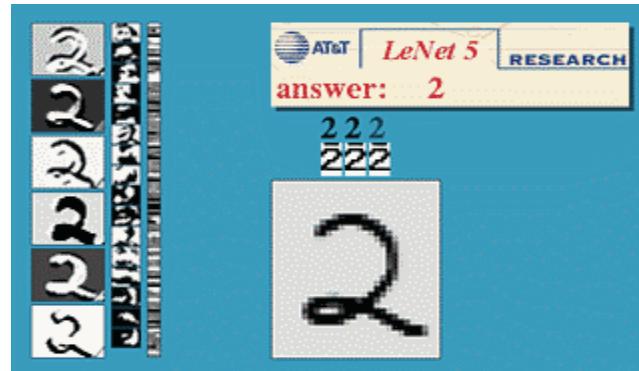

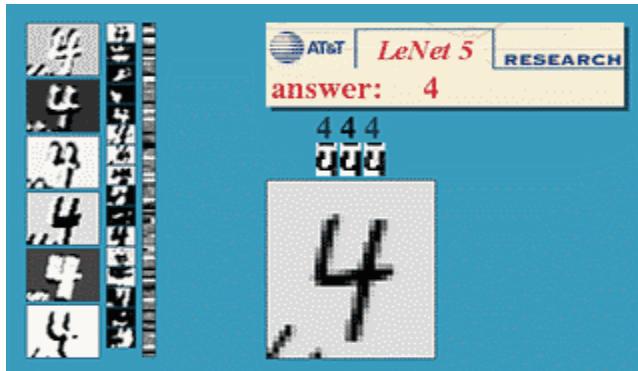

About 14,000 trainable weights

LeNet5 (@LeCun)

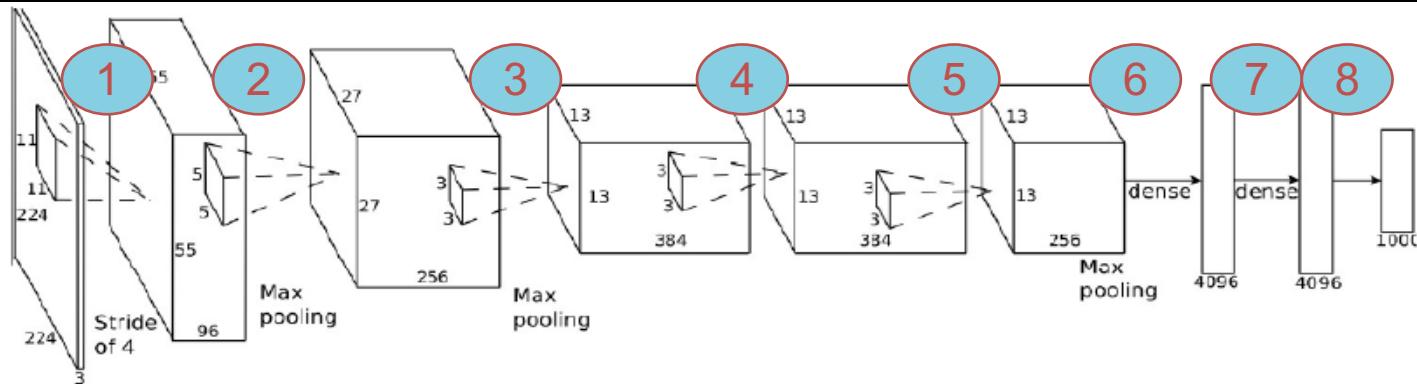

LeNet5 (@LeCun)

AlexNet 2012

- Same model as LeCun'98 but:
 - Bigger model (8 layers)
 - More data (10^6 vs 10^3 images)
 - GPU implementation (50x speedup over CPU)
 - Better regularization (DropOut)

AlexNet 2012

Same type of convnet with

- Filtering (convolution)
- Non-Linearity
- Pooling

8 layers but 224x224 input

images => much bigger model:

- 650,000 neurons
- 60,000,000 weights!

Non-Linearity

• Non-linearity

- Per-feature independent
- Tanh
- Sigmoid: $1/(1+\exp(-x))$
- Rectified linear
 - Simplifies backprop
 - Makes learning faster
 - Avoids saturation issues

→ Preferred option

The figure shows three plots of activation functions. The top row shows the Tanh function (red curve) and the Sigmoid function (green curve). The bottom plot shows the Rectified Linear Unit (ReLU) function, which is zero for x < 0 and increases linearly for x ≥ 0.

Filtering

• Convolutional

- Dependencies are local
- Translation equivariance
- Tied filter weights (few params)
- Stride 1,2,... (faster, less mem.)

The diagram shows the convolution process. An input image of a cityscape is processed by a convolutional layer with a 5x5 kernel. A green box highlights a small portion of the input. Blue arrows show the receptive fields of the kernel, which overlap across the input. The resulting output is a feature map where each pixel is the result of applying the kernel to a local receptive field in the input.

Input Feature Map

Pooling

• Spatial Pooling

- Non-overlapping / overlapping regions
- Sum or max
- Boureau et al. ICML'10 for theoretical analysis

The diagram shows a 3x3 input grid with yellow and blue boxes indicating receptive fields. The top part shows a 2x2 max-pooling step, where the maximum value from each 2x2 receptive field is selected. The bottom part shows a 2x2 sum-pooling step, where the sum of values from each 2x2 receptive field is calculated.

Max Sum

More data for supervised training

ImageNet 2012: the (deep) revolution

- 1.2 million labeled images
- 1000 classes
- Mono-class
- TOP5

Image classification result

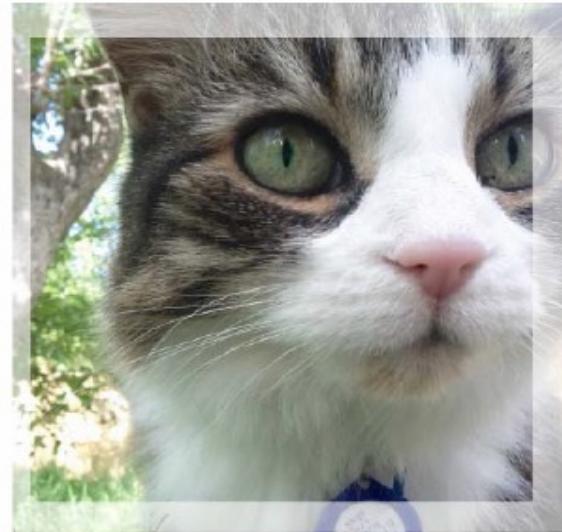

Learning the AlexNet

- Basics:
 - SGD, Backprop
 - Cross Validation
 - Grid search
- “New”
 - Huge computational resources (GPU)
 - Huge training set (1 million images)
 - Data augmentation - Pre-processing
 - Dropout
 - ReLu
 - *Contrast normalization*

Data Augmentation

lots of jittering, mirroring, and color perturbation of the original images generated on the fly to increase the size of the training set

Crop, flip,.. in train AND in test

Dropout: an efficient way to average many large neural nets

For each training example, randomly omit each hidden unit with probability 0.5

Due to sharing of weights, model strongly regularized

Pulls the weights towards what other models want.

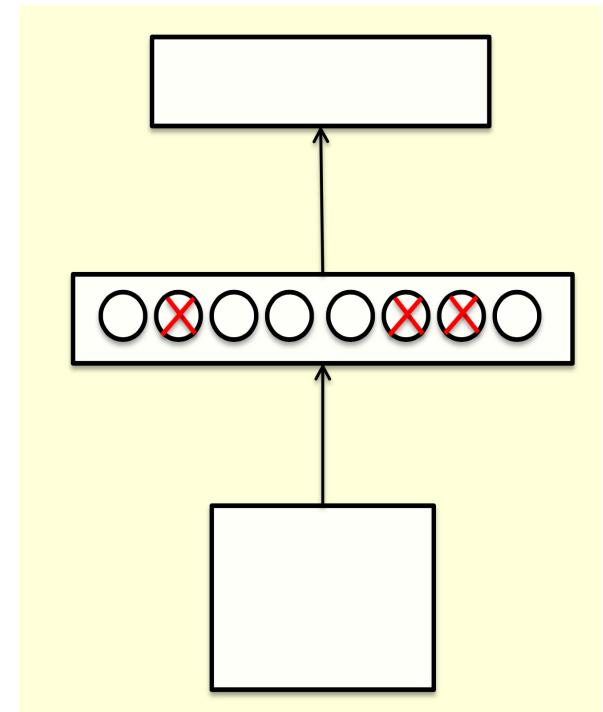

Better than L2 and L1 regularization that pull weights towards zero

Standard Neural Net

After applying dropout.
@Hinton, NIPS 2012

Dropout: what do we do at test time?

Option 1:

Sample many different architectures and take the geometric mean of their output distributions

Option 2: (Faster way)

Use all the hidden units

but after **halving their outgoing weights**

Rq: In case of single hidden layer, this is equivalent to the geometric mean of the predictions of all models

For multiple layers, it's a pretty good approximation and its fast

How well does dropout work?

Significantly improve generalization:

For very deep nets, or at least when there are huge fully connected layers (eg. AlexNet first FC layer, VGG next, ...)

Less useful for fully convolutional nets

Useful to prevent feature co-adaptation (feature only helpful when other specific features present)

Later in course

⇒**Dropout as a Bayesian Approximation**

⇒**Representing Model Uncertainty in Deep Learning**

AlexNet 2012

Ablation study

1. Number of layers
2. *Tapping off features at each layer*
3. Transfo Robustness vs layers

Architecture of Krizhevsky et al.

- 8 layers total
- Trained on Imagenet dataset [Deng et al. CVPR'09]
- 18.2% top-5 error
- Our reimplementation:
18.1% top-5 error

Architecture of Krizhevsky et al.

- Remove top fully connected layer
 - Layer 7
- Drop 16 million parameters
- Only 1.1% drop in performance!

Architecture of Krizhevsky et al.

- Remove both fully connected layers
 - Layer 6 & 7
- Drop ~50 million parameters
- 5.7% drop in performance

Architecture of Krizhevsky et al.

- Now try removing upper feature extractor layers & fully connected:
 - Layers 3, 4, 6 ,7
- Now only 4 layers
- 33.5% drop in performance

→ Depth of network is key

Translation (Vertical)

Scale Invariance

Output

Layer 1

Layer 7

Rotation Invariance

Deep ConvNets for image classification

- AlexNet 8 layers, 62M parameters

Alex Krizhevsky, Ilya Sutskever and Geoffrey Hinton
ImageNet Classification with Deep Convolutional Neural Networks.
In *NIPS*, 2012.

Extra

Comparison BoW / deep CNN

Comparison BoW / CNN deep

1. Regular grid + gradient detection (SIFT) => bank of 8 linear filters (convolution) + Winner Take All (inter-maps) => 8 maps
2. Local histogram SIFT => spatial local sum pooling inside maps on a fixed grid 4x4 => 16x8=128 (smaller) maps
3. BoW Coding = projection on M vectors (visual dico elts) => a bank of M linear filters of size 4x4x8 (=1x1x128 convolution) => M maps
4. BoW Pooling => global pooling on each map => M scalar values = 1 vector representation BoW (extension: SPM)
5. Classification (SVM) => Fully connected layers

BoW = Conv1+pooling(loc)+Conv2+pooling(global)+Fconnected

- Handcrafted+unsupervised vs. end-to-end supervision
- Light deep vs. very deep

Deep vs shallow in Computer Vision

- CV work(ed) a lot on handcrafted local features
 - BoVW (Bag of Visual Words and extensions FisherVectors, BossaNova ...)
 - BoVW not so shallow but not end-to-end supervised learning
- CNN: end-to-end learning on a **handcrafted** architecture! [Chatfield BMVC 2014]
 - Why 8 layers? why 3x3 at the 5th layer without polling? ... => ad-hoc architecture

Zero-padding in convolutional neural network

To avoid shrinking the spatial extent of the network rapidly

No Padding / Padding

No padding 5x5 => 3x3

3 ₀	3 ₁	2 ₂	1	0
0 ₂	0 ₂	1 ₀	3	1
3 ₀	1 ₁	2 ₂	2	3
2	0	0	2	2
2	0	0	0	1

12.0	12.0	17.0
10.0	17.0	19.0
9.0	6.0	14.0

Padding 5x5 => 5x5

Stride 2 conv

More in this [link](#)

More in getting local Invariance

Invariance to local translation (small shift) OK with pooling

Is convolution equivariant/invariant to changes in scale or rotation?

No such invariance with linear filters

Possible extension:

Pooling OVER outputs of separately parameterized convolutions

Become possible to LEARN invariance to rotation (or other)

Example (Bengio et al. Deep Learning 2014):

By learning to have each filter be a different rotation of the “5” template +
pooling over outputs => invariance to rotation of the “5”

5	5	5
5	5	5
5	5	5

“This is in contrast to translation invariance, which is usually achieved by hard-coding the net to pool over shifted versions of a single learned filter”
